Multithreading in Java

Multithreading is a Java feature that allows concurrent execution of two or more parts of a program for maximum utilization of CPU. Each part of such program is called a thread. So, threads are light-weight processes within a process.

Threads can be created by using two mechanisms:

- 1. Extending the Thread class
- 2. Implementing the Runnable Interface

Thread creation by extending the Thread class

We create a class that extends the **java.lang.Thread** class. This class overrides the run() method available in the Thread class. A thread begins its life inside run() method. We create an object of our new class and call start() method to start the execution of a thread. Start() invokes the run() method on the Thread object.

Java code for thread creation by extending the Thread class:

```
class MultithreadingDemo extends Thread
  public void run()
     try
       // Displaying the thread that is running
       System.out.println ("Thread " +
           Thread.currentThread().getId() +
           " is running");
     catch (Exception e)
       // Throwing an exception
       System.out.println ("Exception is caught");
  }
}
```

160110107031 Page 1

```
// Main Class
public class Multithread
  public static void main(String[] args)
     int n = 8; // Number of threads
     for (int i=0; i<8; i++)
       MultithreadingDemo object = new MultithreadingDemo();
       object.start();
}
```

Output:

```
Thread 8 is running
Thread 9 is running
Thread 10 is running
Thread 11 is running
Thread 12 is running
Thread 13 is running
Thread 14 is running
Thread 15 is running
```

Thread creation by implementing the Runnable Interface

We create a new class which implements java.lang.Runnable interface and override run() method. Then we instantiate a Thread object and call start() method on this object.

Java code for thread creation by implementing the Runnable Interface:

```
class MultithreadingDemo implements Runnable
  public void run()
     try
       // Displaying the thread that is running
       System.out.println ("Thread " +
                   Thread.currentThread().getId() +
                   " is running");
     catch (Exception e)
       // Throwing an exception
       System.out.println ("Exception is caught");
```

160110107031 Page 2

```
// Main Class
class Multithread
  public static void main(String[] args)
     int n = 8; // Number of threads
     for (int i=0; i<8; i++)
       Thread object = new Thread(new MultithreadingDemo());
       object.start();
```

Output:

```
Thread 8 is running
Thread 9 is running
Thread 10 is running
Thread 11 is running
Thread 12 is running
Thread 13 is running
Thread 14 is running
Thread 15 is running
```

Thread Class vs Runnable Interface

- 1. If we extend the Thread class, our class cannot extend any other class because Java doesn't support multiple inheritance. But, if we implement the Runnable interface, our class can still extend other base classes.
- 2. We can achieve basic functionality of a thread by extending Thread class because it provides some inbuilt methods like yield(), interrupt() etc. that are not available in Runnable interface.
